Bridge over troubled waters

The Sun, Malaysia

Bridge over troubled waters

COMMENT by Prof Datuk Dr Ahmad Ibrahim

THE world is never free from conflict. It can be over territorial ownership, as seen in Gaza or the pursuit of valuable oil reserves, which has also led to skirmishes.

But increasingly, many see water as the next reason for conflict, which can even escalate into war. Water is a critical resource for life, ecosystems and economic development, yet it faces numerous global challenges. These include scarcity, pollution, unequal access and the impacts of climate change.

Many countries share water resources. Many rivers run through many countries. A good example is the Nile, which flows through countries including Ethiopia, Sudan and Egypt, the main ones. Similarly, the Mekong River is shared by countries in Indochina.

Water scarcity is becoming more prevalent. Over two billion people live in countries experiencing high water stress, and about four billion people face severe water scarcity at least one month per year. Causes include over-extraction of groundwater, population growth and inefficient water use in agriculture, industry and households.

Water pollution is a regular occurrence. Industrial discharge, agricultural runoff (pesticides and fertilisers) and untreated sewage contaminate freshwater sources. Pollutants like microplastics and heavy metals further degrade water quality, threatening human health and ecosystems.

Millions of people, particularly in developing countries, lack access to safe drinking water and sanitation. Marginalised communities, including women and children, are disproportionately affected.

It is no secret that climate change exacerbates water issues by altering precipitation patterns, causing droughts, floods and glacial melt. Rising temperatures increase evaporation rates, reducing water availability in already arid regions.

Transboundary water conflicts have become inevitable. Shared water resources (rivers, lakes and aquifers) often lead to disputes between countries, especially in regions like the Middle East, South Asia and Africa.

Agriculture accounts for 70% of global freshwater use, often inefficiently, leading to depletion of water resources.

Countries are collaborating through treaties and organisations to manage shared water resources. Examples include the UN Water Convention and the Indus Waters Treaty between India and Pakistan.

The Sustainable Development Goal Six aims to ensure the availability and sustainable management of water and sanitation for all by 2030. It is still uncertain whether this can be achieved.

Many countries are adopting water-saving technologies, such as drip irrigation in agriculture and water recycling in industries. They are leading in water conservation, using desalination, wastewater recycling and efficient irrigation systems.

Governments and organisations are building and upgrading water infrastructure, including dams, pipelines and treatment plants. For example, China's South-North Water Transfer Project aims to address water scarcity in the north by diverting water from the south.

Countries are implementing stricter regulations on industrial discharge and agricultural runoff. The European Union's Water Framework Directive sets standards for water quality and ecosystem protection.

Nations are investing in climate-resilient water management, such as rainwater harvesting, flood control systems and drought-resistant crops.

The Netherlands is a pioneer in flood management, using innovative techniques like floating homes and water-absorbing urban designs.

NGOs and governments are working with local communities to improve access to clean water and sanitation. Programmes like WaterAid and Charity: Water focus on providing sustainable water solutions in developing countries.

Advances in technology, such as desalination, smart water metres and AI-based water management systems, are helping optimise water use. Countries like Saudi Arabia and the UAE are investing heavily in

Water is a global issue that requires coordinated efforts at local, national and international levels.

desalination to meet their water needs.

Campaigns to raise awareness about water conservation and sustainable practices are being implemented globally. Schools and communities are being educated on the importance of reducing water waste and protecting water sources.

International financial institutions, such as the World Bank and the Asian Development Bank, are funding water projects in developing countries. Public-private partnerships are also being leveraged to finance water infrastructure and innovation.

Challenges remain in addressing water issues. Many developing countries lack the financial resources to invest in water infrastructure and technology.

Transboundary water disputes and domestic politics can hinder cooperation and implementation of solutions. Rapid urbanisation and population growth increase

pressure on water resources. Predicting and adapting to climate change impacts remains a significant challenge.

Water is a global issue that requires coordinated efforts at local, national and international levels. While progress is being made through technological innovation, international cooperation and community engagement, much work remains to ensure sustainable water management for future generations. Addressing water challenges is not only essential for human survival but also for achieving broader sustainable development goals.

Prof Datuk Dr Ahmad Ibrahim is from the Tan Sri Omar Centre for STI policy and IISDS, UCSI University. He is also an associate fellow at the Ungku Aziz Centre for Development Studies at Universiti Malaya.
